RECURSION AND TREE RECURSION

COMPUTER SCIENCE MENTORS

September 23, 2019 to September 26, 2019

1 Recursion

There are three steps to writing a recursive function:

- 1. Create base case(s)
- 2. Reduce your problem to a smaller subproblem and call your function recursively on the smaller subproblem
- 3. Figure out how to get from the smaller subproblem back to the larger problem

Real World Analogy for Recursion

Imagine that you're in line for boba, but the line is really long, so you want to know what position you're in. You decide to ask the person in front of you how many people are in front of them. That way, you can take their response and add 1 to it. Now, the person in front of you is faced with the same problem that you were trying to solve, with one less person in front of them than you. They decide to take the same approach that you did, by asking the person in front of them. This continues until the very first person in line is asked. At this point, the person at the front knows that there are 0 people in front of them, so they can tell the person behind them that there are 0 people in front. Now, the second person can figure out that there is 1 person in front of them, and can relay that back to the person behind them, and so on, until the answer reaches you.

Looking at this example, we can see that the "recursive function" is trying to figure out how many people are in front of you. The base case is if you are in position 1 (since then there are 0 people in front of you, and you don't have anyone else). The recursive case is if you are in any position greater than 1, since then you can "recursively ask" the person in front of you (which is our smaller subproblem!) Finally, we can get from the smaller subproblem back to the big problem by adding 1 to the number from the person in front of you, since you have to include them in your count.

1. Write a function is_sorted that takes in an integer n and returns true if the digits of that number are nondecreasing from right to left.

```
def is_sorted(n):
    """
    >> is_sorted(2)
    True
    >> is_sorted(22222)
    True
    >> is_sorted(9876543210)
    True
    >> is_sorted(9087654321)
    False
    """
```

2. (Spring 2015 MT1 Q3C) Implement the combine function, which takes a non-negative integer n, a two-argument function f, and a number result. It applies f to the first digit of n and the result of combining the rest of the digits of n by repeatedly applying f (see the doctests). If n has no digits (because it is zero), combine returns result.

2 Tree Recursion

Tree Recursion vs Recursion

In most recursive problems we've seen so far, the solution function contains only one call to itself. However, some problems will require multiple recursive calls – we colloquially call this type of recursion tree recursion, since the propagation of function frames reminds us of the branches of a tree. "Tree recursive" or not, these problems are still solved the same way as those requiring a single function call: a base case, the recursive leap of faith on a subproblem, and solving the original problem with the solution to our subproblems. The difference? We simply may need to use multiple subproblems to solve our original problem.

Tree recursion will often be needed when solving counting (how many ways are there of doing something?) problems and optimization (what is the maximum or minimum number of ways of doing something?) problems, but remember there are all sorts of problems that may need multiple recursive calls! Always come back to the recursive leap of faith.

Two rules that are often useful in solving counting problems:

- 1. If there are *a ways* of doing something and *b ways* of doing another thing, there are *ab ways* of doing **both** at the same time.
- 2. If there are *a ways* of doing one thing and *b ways* of doing another, but we can't do both things at the same time, there are a + b ways of doing either the first thing **or** the second thing.

1. Mario needs to jump over a series of Piranha plants, represented as a string of 0's and 1's. Mario only moves forward and can either *step* (move forward one space) or *jump* (move forward two spaces) from each position. How many different ways can Mario traverse a level without stepping or jumping into a Piranha plant? Assume that every level begins with a 1 (where Mario starts) and ends with a 1 (where Mario must end up).

Hint: Does it matter whether Mario goes from left to right or right to left? Which one is easier to check?

f	<pre>mario_number(level): """</pre>
	Return the number of ways that Mario can traverse the level, where Mario can either hop by one digit or two digits each turn. A level is defined as being an integer with digits where a 1 is something Mario can step on and 0 is something Mario cannot step on. >>> mario_number(10101) 1
	>>> mario_number(11101) 2
	>>> mario_number(100101)
	0
	if:
	elif:
	else:

2. James wants to print this week's discussion handouts for all the students in CS 61A. However, both printers are broken! The first printer only prints multiples of n pages, and the second printer only prints multiples of m pages. Help James figure out whether or not it's possible to print exactly total number of handouts!

<pre>has_sum(total, n, m): """</pre>	
>>> has_sum(1, 3, 5)	
False	
>>> has_sum(5, 3, 5) $\#$ 0 * 3 + 1 * 5 = 5	
True	
$>>> has_sum(11, 3, 5) # 2 * 3 + 1 * 5 = 11$	
True	
п п п	
if	
returnelif	
return	

3. The next day, the printers break down even more! Each time they are used, the first printer prints a random x copies $50 \le x \le 60$, and the second printer prints a random y copies $130 \le y \le 140$. James also relaxes his expectations: he's satisfied as long as there's at least lower copies so there are enough for everyone, but no more than upper copies to prevent waste.

def	<pre>sum_range(lower, upper): """</pre>
	<pre>>>> sum_range(45, 60) # Printer 1 prints within this range True</pre>
	<pre>>>> sum_range(40, 55) # Printer 1 can print a number 50-60 False</pre>
	<pre>>>> sum_range(170, 201) # Printer 1 + 2 will print between 180 and 200 copies total</pre>
	True
	<pre>def copies(pmin, pmax): if:</pre>
	return
	elif:
	return
	return
	return copies(0, 0)
